catalysis and catalyst is a key technology to solve the problems in energy and environment issues to sustain our human society we believe that comprehensive understanding of the catalysis and catalyst provides us a chance to develop a new catalyst and contributes greatly to our society however the eld of heterogeneous catalyst is dif cultto study andstill stays behindmoredeveloped elds of chemistry such as organic and physical chemistries this is a dilemma to the chemists who study the catalysis and catalyst while we can accomplish the progress in the dustrial application

the scienti c understandingis not complete yet a gap between the useful application and incomplete scienti c understanding however becomes smaller and smaller in recent years because zeolites are ne crystals and the structure is clearly known the study on the catalysis using the zeolites is easier than those encountered in other catalysts such as metals and metal oxides very fortunately zeolites provide us the strong acidity with the ne distribution which enables various useful catalytic reactions when some metals and cations are loaded in close to the acid sites these loadede ments show extraordinarycharacters and many catalytic reactions proceed thereon

this indispensable two volume handbook covers everything on this hot research field the first part deals with the synthesis modification characterization and application of catalytic active zeolites while the second focuses on such reaction types as cracking hydrocracking isomerization reforming and other industrially important topics edited by a highly experienced and internationally renowned team with chapters written by the who s who of zeolite research

zeolites occur in nature and have been known for almost 250 years as alumino silicate minerals examples are clinoptilolite mordenite offretite ferrierite erionite and chabazite today most of these and many other zeolites are of great interest in heterogeneous catalysis yet their naturally occurring forms are of limited value as catalysts because nature has not optimized their properties for catalytic applications and the naturally occurring zeolites almost always contain undesired impurity phases it was only with the advent of synthetic zeolites in the period from about 1948 to 1959 thanks to the pioneering work of r m barrer and r m milton that this class of porous materials began to playa role in catalysis a landmark event was the introduction of synthetic faujasites zeolite x at first zeolite y slightly later as catalysts in fluid catalytic cracking fcc of heavy petroleum distillates in 1962 one of the most important chemical processes with a worldwide capacity of the order of 500 million t a compared to the previously used amorphous silica alumina catalysts the zeolites were not only orders of magnitude more active which enabled drastic process engineering improvements to be made but they also brought about a significant increase in the yield of the target product viz motor gasoline with the huge fcc capacity worldwide the added value of this yield

enhancement is of the order of 10 billion us per year

the chemistry of microporous materials is among the most rapidly developing fields of chemical research it is extended from the conventional zeolites which are mineral aluminosilicates with microporous host lattice structures both zeolites and microporous crystalline materials are molecular sieves which possess open frameworks in which guest species like water and amines or quaternary ammoniums known as templates can be accommodated upon the removal of guest species they demonstrate adsorptive and catalytic properties owing to their surface activity as well as the selective character of the structural frameworks there is a huge population of zeolite scientists in china who conduct intensive and interesting studies on these

materials the present review volume intends to draw an outline of the major research activities and achievement in the area of zeolite science in china

the idea for putting together a tutorial on zeolites came originally from my co editor eric derouane about 5 years ago i rst met eric in the mid 1980s when he spent 2 years working for mobil r d at our then corporate lab at princeton nj he was on the senior technical staff with projects in the synthesis and characterization of new materials at that time i managed a group at our paulsboro lab that was responsible for catalyst characterization in support of our catalyst and process development efforts and also had a substantial group working on new material synthesis hence our interests overlapped considerably and we met regularly after eric moved back to namur initially we maintained contact and in the 1990s we met a number of times in europe on projects of joint interest it was after i retired from exxonmobil in 2002 that we began to discuss the tutorial concept seriously eric had semi retired and lived on the algarve the southern coast of portugal in january 2003 my wife and i spent 3 weeks outside of lagos and i worked parts of most days with eric on the proposed content of the book we decided on a comprehensive approach that ultimately amounted to some 20 chapters covering all of zeolite chemistry and catalysis and gave it the title zeolite chemistry and catalysis an integrated approach and tutorial

zeolite zsm 12 was identified as a promising candidate for hydroisomerization of n alkanes and a large part of the work was focused on the preparation of zsm 12 and studying its catalytic performance reliable and efficient methods for synthesis of zsm 12 with high levels of acidity were not available in the literature through systematic studies the synthesis was greatly simplified and zsm 12 was successfully crystallized at a relatively low si al ratio of 30 using tetraethylammonium cations as the template in the hydroisomerization of n heptane as well as mixtures of n alkanes zsm 12 catalysts provided a significantly higher selectivity to both monobranched and dibranched isomers compared to other large pore zeolites kinetic studies carried out using individual octane isomers showed that the formation of certain dibranched and tribranched isomers was mildly hindered by the shape selective effect of the zsm 12 pore which resulted in the higher isomer yield it was found that the cracking activity of zsm 12 could be increased by three to four times by carrying out the calcination to remove the template at temperatures higher than what is normally used the variation of the cracking activity with respect to the calcination temperature was very unusual only the samples calcined in two separate narrow temperature ranges showed substantially enhanced activity extensive ftir characterizations with pyridine adsorbed on the acidic zeolite indicated that the enhancement in the cracking activity was due to a synergistic interaction between the framework brn sted acid sites and a lewis acidic extra framework aluminum possibly cationic species present in the zeolite hydroisomerization of n heptane was studied over large pore zeolites with different acidity properties and wide range of si al ratios the performance of zeolite catalysts with enhanced activity were very sensitive to the platinum precursor used and the pretreatment conditions the results suggested that zeolite acidity characteristics do not affect the isomer yield provided the catalyst is carefully prepared to ensure good metal acidity balance therefore it appears that the only way to obtain isomer yields higher than that of y zeolite is by employing shape selective zeolites
